Chapter 2: Introduction to Statistical Inference 17

DIFFERENT TYPES OF DATA 18

Every measurement is limited by imperfections in precision and accuracy 19
The 30–300 rule is used to determine the proper instrument of measure 20
The rules of significant figures define the precision of any measurement 22

FOR EVERY MEASURE THERE IS ERROR 22

Descriptive assessments of central tendency are used for accurate representations of the variability in a sample 24
"Normal" data can be plotted as a gaussian curve 27
The coefficient of variation can be used to measure variability 28
Data distributions that aren't normal often follow a poisson distribution 30
Nonnormal datasets can be normalized using data transformation 30
The central limit theorem can be employed to increase the predictability of your data distributions 31

INFERENTIAL STATISTICS: A BRIEF PRIMER 33

The probability level will define which results are statistically significant, and which are not 33
The use of confidence intervals and outliers helps in the analysis of statistical significance 34
The strength of our statistical analyses will depend heavily on our assumptions of the data 34
Independence 35
Single population 36
Normality 36
Homoscedasticity 36
Formulating a testable hypothesis is critical to both the scientific method and the use of inferential statistics 37
The most basic statistical tests are used to test for equality (or inequality) between two populations 38

CHOOSING THE RIGHT STATISTICAL METHOD 40

Unit 2 Methods of Data Acquisition

Chapter 3: Experimental Design 45

STARTING WITH THE BASICS OF EXPERIMENTAL DESIGN 46

Method comparison 47
Single-element monitoring and assessment 48
Multiple-element correlation or causation 48
Complex synthetic analysis 49
Proper experimental design requires significant preparation 49
Literature review 49

Data requirements 50
Research strategy 50
Scope of investigation 50
Equipment and facilities needs 51
Preliminary site survey(s) 51
Sampling effort 51
Sample size determination is the key to success in every research endeavor 53
Dichotomous variables can be used to determine n_o 53
Continuous variables can also be used to determine n_o 54
AN INTRODUCTION TO QUANTITATIVE SAMPLING METHODS 55
BASIC PLOT METHODS 56
Sampling effort 56
Plot shape 56
Plot size 58
Random sampling 59
Simple random sampling is the foundation of most field methods 60
Stratified random sampling can be used to organize the study area into horizontal or vertical strata 60
Transect interval sampling is a variation of the belt/line transect method 61
Adaptive sampling is an excellent method for detecting rare events 63
BASIC PLOTLESS METHODS 63
Plotless density estimators (PDEs) do not require exhaustive surveys of an area 63
Basic distance estimators (BDEs) 64
Ordered distance estimators (ODEs) 64
Angle-order estimators (AOEs) 64
Line transect density estimators (LTDEs) are the best PDE for "line-of-sight" search patterns 66
Variable area transect (VAT) 66
The strong method (SM) 67
Plotless methods for mobile subjects require a strategy different than most PDEs 67
Roaming surveys 67
Mark and recapture 68
Catch per unit effort (CPUE) 68

Chapter 4: Oceanographic Variables 69

ESTABLISHING THE FRAME OF REFERENCE 70
DEFINING SPATIAL AND TEMPORAL BOUNDARIES 71
Distance measures are a simple but critical way to define spatial relationships 72
Depth measures are used to extend spatial relationships into the vertical dimension 72
Time is required to define the succession of events 73
PHYSICAL VARIABLES FOR CONSIDERATION AND THE ESSENTIAL MEASURES OF OCEAN PHYSICS 75
Mass is the most important way to quantify existence 75
Temperature affects the physical properties of all matter 76
Hydrostatic pressure is used to describe the potential energy within a fluid 77
Density describes the relationship between matter and the space it occupies 78
SUPPLEMENTAL MEASURES OF OCEAN PHYSICS 78
Flow fields (and currents) are used to describe both the speed and direction of water movement 78
Wave geometry is used to discern wave patterns in a complex ocean 80
Tides represent the influence of heavenly bodies on ocean dynamics 80
Secchi depth is used as a simple way to define the optical properties of water 80
CHEMICAL VARIABLES 81
Salinity is the fundamental measure of salt content in the ocean 82
Conductivity represents an indirect way to measure salinity using electricity 83
Metabolic nutrients are dissolved molecules which are necessary for life in the ocean 83
SUPPLEMENTAL MEASURES OF OCEAN CHEMISTRY 84
Structural nutrients are dissolved molecules which can form solid mineral deposits 84
Dissolved O_2 is one of the most influential molecules that affects the biogeochemistry of the ocean 84
Dissolved CO_2 can be used to investigate gas exchange and ocean acidification dynamics 84
BIOLOGICAL VARIABLES 85
Species identification is the only way to describe the diversity of life in the ocean 85
Species abundance and biomass measures are used to quantify the amount of biologic matter 85
Species biometrics represent those measures that suggest a specific biological function 86
SUPPLEMENTAL MEASURES OF OCEAN BIOLOGY 87
Accessory pigments can be used to identify different species of plants and algae 87
Organic C-N-P ratios define the nutritional status of the living biomass 87
Age structure and size class measures establish the demographics within a specific population 87

GEOLOGICAL VARIABLES 87
Geomorphology and bathymetry describe the complex geometry at the ocean boundaries 88
Suspended sediments provide the critical link between land and sea 88
SUPPLEMENTAL MEASURES OF OCEAN GEOLOGY 89
Sediment grain characteristics provide forensic evidence of historical events 89
OTHER VARIABLES 89
Winds provide a strong influence on flow fields and surface currents 89
Barometric pressure can affect the hydrostatic pressure of ocean water beneath it 90
Air temperature can provide a delayed influence on water temperature 90
Precipitation will affect both the temperature and salinity of surface water in the ocean 90
REFERENCES 91
FURTHER READING 91

Chapter 5: Common Hydrologic Census Methods 93

THE DIFFERENCE BETWEEN HYDROLOGY AND HYDROGRAPHY 94
WHEN TO MEASURE HYDROLOGIC DATA 94
Continuous sampling methods are best when measuring rapidly changing hydrologic variables 95
Underway systems provide continuous sampling during transit between multiple locations 95
Moored systems provide continuous sampling at fixed locations only 96
Discrete sampling methods are best when measuring slowly changing hydrologic variables 97
WHERE TO COLLECT HYDROLOGIC DATA 99
Proper site selection is the key to success for any sampling strategy 99
Fluvial study sites are those located along streams and rivers 100
Lacustrine and estuarine study sites are those located in bays and inland coastal areas 101
Marine study sites are those located along the coast or out to sea 102
Don't forget the vertical dimension when planning your study sites 102
HOW TO MEASURE HYDROLOGIC DATA 104
Colorimetric analysis uses color as a method to quantify hydrologic parameters 104
Titrimetric analysis quantifies hydrologic parameters by inducing a specific chemical reaction 105
Electronic analysis measures small changes in conductance to quantify hydrologic parameters 105
REFERENCES 106
FURTHER READING 106

Chapter 6: Census Methods for Benthic Organisms 107

CHOOSING THE RIGHT METHOD FOR EACH BIOTIC HABIT 108
Starting simple is the key to every biological census 109
Take note whether the census includes open or closed populations 109
Benthic organisms require a two-dimensional census method 110
CENSUS METHODS FOR THE SESSILE BENTHOS 111
Rare species are best surveyed using the T-square plotless method 111
The distance sampling plot method is best for closed populations 112
The line transect plot method is among the simplest to use 113
True area surveys are accomplished using quadrat plot methods 114
Long-term studies may require a fixed quadrat plot method 116
CENSUS METHODS FOR THE MOTILE BENTHOS 117
Trapping and removal methods are the most common census strategy for motile benthic specimens 117
Pitfall traps are best for capturing small, motile species above sea level 119
Attractant traps are excellent for capturing forager and scavenger species 119
Emergence traps are best used in the capture of cryptic species 120
Enclosure and exclosure traps are best suited for mesocosm studies 121
Mark-and-recapture methods are a "trapless" solution to census motile species 121
The pseudo-removal method can be used to estimate the size of a closed population by simply marking specimens 122
The wileyto removal method for closed populations uses a combination of marked and removed specimens to assess population size 122
The multiple mark-and-recapture (schnabel) method for closed populations is among the most rigorous estimates of population size 123
Open populations are more challenging to assess and require complex multiple mark-and-recapture methods 124

REFERENCES 124
FURTHER READING 124

Chapter 7: Census Methods for Pelagic Organisms 125

LIFE IN A FLUID MEDIUM 126
Pelagic surveys require a definition of the vertical dimension 126
Size matters when choosing the proper gear and method for pelagic surveys 129
CENSUS METHODS FOR VIRUSES, BACTERIA, AND SMALL PHYTOPLANKTON 131
Virio- and bacterioplankton census methods require specialized equipment 132
Small (<10 μm) phytoplankton are most effectively collected by bottle 133
CENSUS METHODS FOR LARGE PHYTOPLANKTON, ZOOPLANKTON, AND LARVAE 133
The geometric dimensions of a plankton net determine its ideal function 133
Choosing the appropriate type of plankton tow requires some knowledge of the target organisms' vertical distribution in the ocean 135
The horizontal tow is best for sampling at a single, discrete depth layer 135
The vertical tow is best for integrated sampling of the entire water column 138
The double-oblique tow offers the best of both worlds, combining features of the horizontal and vertical tows 138
Plankton quantitation requires knowledge of the filtered volume of seawater 139
The sample volume from a plankton tow can be used to derive the population density of plankton in natural waters 141
Plankton Samples Must Be Properly Preserved for Later Analyses 141
The methods for processing plankton rely on representative subsamples 142
Counting and identifying plankton is a visual enterprise 143
CENSUS METHODS FOR FISHES AND OTHER NEKTON 144
Biometry statistics are critical to nekton surveys 146
The natural abundance of nekton can be estimated using "Catch PerUnit effort" (CPUE) data 147
NETS OR HOOK-AND-LINE CAPTURE METHODS FOR NEKTON 148
Seine nets can be easily deployed in shallow water by boat or by hand 148
Trawl nets are used in deeper waters and require the use of a vessel 149
Dredges must be pulled along the bottom to collect benthic organisms 150
Cast and push netting are best suited for use in bays, tidal creeks, and other small coastal areas 150
Gill netting is used to collect specimens from vast open-water areas, over extended periods of time 151
Trapping allows the collection of specimens that are unharmed during their capture 151
Hook and line methods are typically more selective than gill netting 151
How to define "effort" within CPUE analyses, based on the capture method 152
ANALYSIS OF PELAGIC COLLECTIONS 153
REFERENCES 153

Unit 3 Methods of Data Analysis

Chapter 8: Introduction to Univariate Analysis 157

THE FOUNDATIONS OF UNIVARIATE ANALYSIS 158
Univariate comparisons must be structured to possess only one scaled variable 159
COMMON STATISTICAL METHODS FOR UNIVARIATE ANALYSIS 162
The most common statistical tool for univariate analysis is the *t* test 163
The appropriate use of the *t* test depends on three critical assumptions 165
The single-sample *t* test is used to compare measurements against a historical or theoretical value 166
The paired-sample *t* test is used to test the dependence between two populations 166
Variance is used to determine whether to use the pooled-sample or welch's *t* test 167
The pooled-sample *t* test assumes equal variances between the populations being compared 168
Welch's *t* test is used when the variances of two populations are not equal 169
The one-way analysis of variance (ANOVA) is used to compare multiple populations simultaneously 169
COMMUNITY COMPARISONS USING UNIVARIATE ANALYSIS 171
Measures of species richness are the easiest way to compare communities 171
Simple community comparisons can be performed using ranked abundance data and the DAFOR/SACFOR methods 172
Biodiversity and its related measures are the cornerstones of community comparison methods 173

USING THE BEFORE-AFTER-CONTROL-IMPACT (BACI) APPROACH 177
MOVING BEYOND THE SIMPLICITY OF UNIVARIATE ANALYSIS 178
REFERENCES 179
FURTHER READING 179

Chapter 9: Introduction to Multivariate Analysis 181

INTRODUCTION TO CORRELATION ANALYSIS 182
Correlation analysis can only be performed among continuous variables 182
Correlation analysis can be used on no more than two dependent variables at a time 183
LINEAR REGRESSION ANALYSIS 184
Correlations among normal data can be tested using pearson's correlation coefficient 185
Correlations among nonnormal data can be tested using spearman's ranked correlation coefficient 187
Correlations can also be used to make predictions using regression analysis 187
Regression analysis is used to test hypotheses and define confidence intervals within predictive mathematical models 189
MULTIPLE REGRESSION AND CURVE ESTIMATION 191
Multiple regressions that are nonlinear must be determined using curve estimation 194
CORRELATION BETWEEN TWO DEPENDENT VARIABLES 195
Canonical correlation (CC) is used to explore correlations between two sets of dependent variables 195
Principal component analysis (PCA) is used to create two new sets of dependent variables and explore their correlation 196
FROM MEASUREMENTS TO MODELS 197

Unit 4 Methods of Data Assimilation (Modeling)

Chapter 10: Fundamental Concepts in Modeling 201

SO WHAT IS A MODEL? 202
MATHEMATICAL MODELS AS SCIENTIFIC TOOLS 204
USING CONCEPTUAL DIAGRAMS 206
THE FUNDAMENTAL ELEMENTS OF MODELING 207
Forcing functions are the fundamental equations that define the mathematical structure of the model 207
Variables are those elements within the model that can be quantified, and whose values are likely to change 208
Parameters and constants differ from variables in that they represent fixed quantities that do not change 209
FROM CONCEPT TO CREATION: WHAT NOW? 209
REFERENCES 210
FURTHER READING 210

Chapter 11: Model Structure 211

DEFINING SPACE AND TIME 212
Zero-dimensional models simulate what occurs at a single point 212
One-dimensional models simulate what occurs along a line 213
Two-dimensional models simulate what occurs within a defined area 214
Three-dimensional models simulate what occurs within a fixed volume 215
Spatial dimensions must be resolved using a model grid 215
CARTESIAN GRIDS 216
TELESCOPING GRIDS 217
CURVILINEAR GRIDS 218
UNSTRUCTURED GRIDS 218
VERTICAL GRIDS 218
The model timestep is used to resolve the temporal dimension 218
Striking a balance between model resolution and stability is paramount 220
BOUNDARY CONDITIONS 220
COMPUTATIONAL SCHEMATA 222
Model currency is the unifying medium of exchange between variables within the model 223
Mass and energy budgets must obey the law of conservation 223
Model initialization requires that we begin with a "filled" model domain 224
REFERENCES 229
FURTHER READING 229

Chapter 12: Modeling Simple Dynamics 231

CONSTRUCTING YOUR FIRST MODEL 232
The first rule of model construction: do your homework 232
The second rule of model construction: follow your conceptual model 233
The third rule of model construction: use the appropriate arrays 234
The fourth rule of model construction: define the boundary conditions 235
The fifth rule of model construction: establish your refuges 235
The sixth rule of model construction: stay within your mass budget 236
The unwritten rule of model construction: check your submodels for goodness of fit 237
EXAMPLES OF MODELING SIMPLE DYNAMICS 239
Example 1: nitrogen dynamics of nitrification 239
Example 2: nitrogen dynamics of excretion 241
Example 3: nitrogen dynamics of production 243
REFERENCES 243
FURTHER READING 244

Chapter 13: Modeling Complex Dynamics 245

EMBRACING COMPLEXITY IN OUR MODEL(S) 246
Complex processes are more easily linked by converting your conceptual models to conceptual equations 246
A variable-oriented perspective will help you focus on what goes into (and what comes out of) each modeled process 246
A process-oriented perspective will help you focus on which submodels should be included 247
Conceptual equations are the best way to visualize how submodels should be connected with each other 248
EXAMPLES OF MODELING COMPLEX DYNAMICS 249
Example 2 revisited: complex nitrogen dynamics of excretion 250
Example 3 revisited: complex nitrogen dynamics of assimilation/production 256
MOVING ON TO BIGGER AND BETTER MODELS 260
REFERENCES 261
FURTHER READING 261

Chapter 14: Modeling Large System Dynamics 263

PUTTING IT ALL TOGETHER 264
TYPICAL HYDRODYNAMIC MODEL ELEMENTS 266
Hydrodynamic models are solved by defining the forces at work within the spatial and temporal domain of fluid motion 266
The unequal distribution of mass, as it relates to water density, creates pressure-gradient forces that influence water movement 268
Frictional forces in the ocean play a significant role in water movement 269
The influence of tides is as varied as it is powerful 269
TYPICAL BIOGEOCHEMICAL MODEL ELEMENTS 270
The fundamentals of chemistry are the backbone of biogeochemical models 270
Inorganic chemicals define the chemical nature of seawater, divorced from biology 270
Organic chemicals in seawater are the calling cards of life 271
Bacteria provide a fundamental link between the organic and inorganic chemistry of the sea 272
Diagenesis represents the fusion of geology and chemistry 273
TYPICAL RADIATIVE MODEL ELEMENTS 273
Light and heat must penetrate the atmosphere before they reach the ocean 273
The radiation reaching the ocean surface is quickly attenuated as it travels through the water 275
TYPICAL ECOLOGICAL MODEL ELEMENTS 277
Growth (∂g) describes the positive increment of biomass either from production among autotrophs or assimilation among heterotrophs 277
Diffusive and advective transport (∂X) move biomass throughout the domain in the horizontal dimension 278
Vertical migration and sinking (∂Z) move biomass throughout the domain in the vertical dimension 278
Reproduction (∂Y) represents the fraction of growth that is invested in the next generation 278
Respiration (∂R) is the loss of biomass attributed to gaseous wastes 278
Excretion (∂E) is the loss of biomass attributed to liquid wastes 279
Egestion (∂F) is the loss of biomass attributed to solid wastes 279
Mortality (∂M) is always represented as a loss of biomass, but it comes in many forms 279
